ABSTRACT

The measurement of temperature by using appropriate sensors and controllers is not only important in environmental or weather monitoring but also crucial for many industrial processes. This review covers the study of PLC, microcontrollers and sensors which will be beneficial to readers in understanding the difference between application of PLC and Microcontrollers in controlling temperature. A comparison is also made among three types of smart temperature sensors. A complete analysis is done by using smart sensors with computer support.

Keywords: Microcontrollers, PLC, Smart Temperature Sensors.

I INTRODUCTION

Temperature is defined as the average energy of microscopic motions of a single particle in the system per degree of freedom. Temperature measurement and control plays a key role in industries and home applications, such as, in boilers \cite{1}, greenhouses \cite{2}, ovens, rooms \cite{3}, LEP2 SC RF cavities \cite{4}, turbogas units \cite{5}, geothermal power plants \cite{6}, weather monitoring \cite{7} etc. it is widely used. To sense temperature, sensors are used. A sensor is a device that measures a physical quantity and converts it into a signal which can be read by an observer or by an instrument, like; a mercury thermometer converts the measured temperature into expansion and contraction of a liquid which can be read on a calibrated glass tube \cite{8}.

Temperature monitoring is the process of recording temperature over defined period of time. In previous publications, temperature was monitored with the help of data loggers. Earlier, development of data logger was done through manual measurements from analog instruments. Unfortunately, the data logger was not able to fulfill the requirements of present scenario in terms of time and accuracy. A further development in data logging took place in early 1990s, after which researchers began to design PC based data logging systems \cite{9}. In later stages of development, it was seen that microcontrollers proved to be a reliable and efficient controller \cite{10}. A revolutionary change was seen by use of microcontrollers in embedded system designs. But microcontrollers were difficult to program and cannot be used in harsh environmental conditions. So, PLCs \cite{11} were introduced to overcome the problems of microcontrollers \cite{12}. Temperature control is a process in which change of temperature of a space (and objects collectively there within) is measured or otherwise detected, and the passage of heat energy into or out of the space is adjusted to
achieve a desired average temperature [13]. The scope of this review is to analyze various methods used in control and measurement of temperature.

II OVERVIEW OF CONTRIBUTIONS

In early 1990s, data loggers were used in temperature monitoring applications [9]. With the advancement in technology, microcontrollers were implemented in the field of monitoring [24]. But, microcontrollers performance gets affected by external factors like humidity, temperature variations etc [1]. All these factors led to development of PLC as a controller. PLCs are reliable in harsh environment and are designed to handle many inputs and many outputs [11]. PLCs are easier to program than microcontrollers [12].

TABLE I describes about different types of sensors and processing elements used in various systems of temperature measurement and control. The following points briefly describes about the above mentioned systems:

- The sensor LM 35 can be combined with microcontrollers like PIC18F452, AT89S52 and PLCs. The use of LM 35 with PIC18F452 controller [14] provides a system which is useful in measurement and control of high temperature applications like in boiled water temperature measurement [14] and in industries to control high temperature. LM 35 can also be used with AT89S52 controller for water temperature control, control of room temperature and light [17] [22] by using ANFIS (adaptive neuro fuzzy inference system) and comparing output of the system with PID controller, neural network controller [17]. LM 35 functions with PLC for usage in geothermal power plants [6]. LM35 is low cost, highly effective and efficient in usage [6]. 89C51RD2 is interfaced with LM35 sensor to control the
variation of ambient temperature [13]. This system is used in pharmaceuticals and in ayurvedic medicine manufacturing [13].

- **LM35DZ**, a modified version of LM 35 sensor is used with PIC16F84 microcontroller for temperature monitoring [15]. PIC16F84 has advantage of using flash memory over the other microcontrollers. Flash memory makes programming easier in high level language [15].

- **PT100** is used for high temperature measurement applications like temperature measurement of LEP2 SC RF (LEP2 superconducting radio frequency) cavities [4].

- **SMT 160-30** is a compact temperature transducer used with PIC 16C65A to monitor air temperature [8]. SMT 160-30 is also used with PIC16F877A for measurement of temperature of hot plate and weather monitoring system [23] [7].

- **LM 335** is a temperature sensor which works at -40 degree centigrade to 100 degree centigrade [16]. LM 335 is interfaced with PIC18F4620 to measure the temperature of laboratories and test rooms [16].

### III EXPERIMENTAL SETUP

The hardware and software description of the embedded system for monitoring and controlling of temperature is described in the following section –

#### 3.1 Hardware Description

Temperature measurement and control system can be divided into following sections-

- **Power supply section** - The regulated supply section mode made with full wave rectifier, which provides a constant voltage of 5 volts to the circuit and constant voltage of 12 volts to relays.[9]

- **Analog to digital conversion section** - Since we have to sense analog parameters i.e. temperature and hence we have to use analog to digital converter. We normally opt for ADC0809 [13] as it has 8 channels and is microprocessor compatible ADC. It converts the analog signal of transducer to digital value with respect to reference voltage, which is in most of the cases 2.5 volts. This reference voltage is obtained using TL431, which is programmable shunt voltage reference. With output voltage range 2.5-36 volts and works like zener diode for the conversion. ADC requires a reference frequency, which is supplied by astable oscillator. In most of the cases, the astable oscillator is 555 IC. The conversion frequency is kept around 150 Khz. Sensors used for temperature is LM 35 [6], PT100 [10] [8] and RTD [13]. These sensors are calibrated in degree centigrade and are linear in our working range with 0.5 degree centigrade of accuracy [9].

- **Control section** - The analog value is converted to digital value by ADC and is picked up by microcontroller such as AT89S52 [21], which is a 40 pin device. The AT89S52 is a low power, high performance CMOS 8-bit microcomputer with 8k bytes of flash memory (EPROM) [16].

- **Display Section** - A liquid crystal display is used to display the data we get from microcontroller or PLC. It is a 2X16 line display [18] [19].

- **Temperature Control Section** - This section consists of 12 volts relay control hardware connected to various types of cooling elements such as fans, heating elements etc [20][21].
3.2 Description

A review of researches on temperature measurement and control shows that systems are developed considering the accuracy and cost effectiveness. Temperature control is mainly divided into three sections:

- Sensing elements [8]
- Data processing elements [18]
- Temperature Controlling elements [15][10]

3.2.1 Sensing Elements

Sensing elements are the elements that receive a signal or stimulus (as heat or pressure or light or motion etc.) and responds to it in a distinctive manner. Sensors used for temperature control are:

- Thermocouples [8]
- Thermisters [22]
- Resistance temperature detectors [4][13]
- IC temperature sensors [3][16]

With time thermocouples, thermisters, RTDs were replaced by IC temperature sensors like LM 35 [17], SMT 160-30 [23][7], DS 1820 [8]. The mostly used temperature sensor IC’s are:

3.2.2 SMT 160-30

Transducer SMT 160-30 is a compact temperature transmitter with output signal in pulse width form, suitable for computer processing [23]. Transducer has 3-pin package with 2 pins for voltage (5 V) and one pin for output signal. Measured temperature is given by:

![Figure 1: Block Diagram for Experimental Setup][9]
\[ T \, (w) \, T \, (p) = 0.320 + 0.00470T \]  \hspace{1cm} (1)

- \( T \) = measured temperature
- \( T \) (w) = width of pulse
- \( T \) (p) = period of output signal

### 3.2.3 LM 35

Transducer LM 35 is compact temperature transmitter with analog voltage output + 10 mV/°C [14]. Output signal is on the whole range linear and is calibrated on °C. This output signal is ideal for digital signal processing by A/D converter [3].

### 3.2.4 DS 1820

Single circuit smart temperature sensor DS1820 converts temperature in number form and communicates with environment by the one-wire DALLAS bus [8]. Circuit is made on 3-pin or 16-pin package. Sensor can be loaded by voltage through data bus. Final temperature is given by:

\[ t = T - 0.25 + \left( \frac{N (j) - N (z)}{N (j)} \right) \]  \hspace{1cm} (2)

- \( t \) = final temperature
- \( N (j) \) = number of oscillations corresponds to 1 degree centigrade
- \( N (z) \) = number of oscillation cycle corresponds to zero

<table>
<thead>
<tr>
<th>Temperature sensor</th>
<th>Loading voltage variation</th>
<th>Temperature range</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMT160-30</td>
<td>475-700 volts</td>
<td>(-45) – 130 degree Centigrade</td>

</tr>
</tbody>
</table>

TABLE II gives a comparative overview of IC temperature sensors. The loading voltage requirement is maximum in SMT 160-30 while it is minimum in DS1820. LM 35 is widely used because of its extended working temperature range [8].

### 3.3 Data Processing Elements

Data processing elements are the elements which process the signal provided by transducers [13]. In case of temperature measurement and control, the data processing elements are:

- Microcontroller
- PLC

#### 3.3.1 Microcontroller

A microcontroller is a small computer on a single integrated circuit containing a processor, memory, and programmable input/output peripherals. Program memory is also included on chip and a small amount of RAM. Microcontrollers are designed for embedded applications [24].

---

www.ijarse.com
3.3.2 PLC

PLC is defined as programmable logic controller. Unlike general-purpose computers, the PLC is designed for multiple inputs and output arrangements, extended temperature ranges, immunity to electrical noise, extreme weather and resistance to vibration and impact [11]. Therefore, PLCs are preferred over microcontrollers [5][12].

3.4 Temperature Controlling Elements

Controlling elements are used to control the temperature of the surroundings. There are two types of controlling elements- heating elements and cooling elements.

IV RESULT ANALYSIS

The various systems formed by using temperature sensors and controllers have its own merits and demerits. The result analysis of such systems is given by TABLE III.

IV CONCLUSION

A framework has been presented that incorporates the use of sensors in developing low cost and high accuracy temperature control system using analog and digital components. The performances of sensors are distinguished on the basis of their accuracy. The accuracy indicates how closely the sensor can measure the actual or real world parameters.

Besides, a comparison on the features of different types of monitoring system has been carried out and it concludes that the use of microcontroller makes the system very compact, reliable and very accurate to achieve precise output with real time signals and PLC is beneficial where reprogramming is required and additionally it require minimum maintenance.
