#### ABSTRACT

The moduli set  $\{2n - 1, 2n, 2n + 1\}$  has been commonly used in residue number system (RNS)-based calculations. Its sign extraction problem, even though fundamentally important in magnitude comparison and other difficult algorithms in RNS, has received considerably less attention than its scaling and reverse conversion problems. This paper presents a new algorithm for the design of a fast adder-based sign detector. The circuit is greatly simplified by minimizing the dynamic range to eliminate large modulo operations with the help of the new Chinese remainder theorem. Our synthesis results show that the proposed design outperforms all the existing adder-based sign detectors reported for this moduli set in area and speed.

### Keywords: Chinese remainder theorem (CRT), computer arithmetic, residue number system (RNS).

## **I. NTRODUCTION**

Residue number system (RNS) is gaining enhancing popularity in the VLSI implementation of applicationspecific digital signal processors (DSPs). This is in part due to its ability to accelerate and to decrease the power consumptions of crucial and frequently used data path operations by subword-level parallelism and modularity, and in part due to the ease of realizing modulo operations using the moduli of the forms  $2^n$  and  $2^n\pm 1$ . Modular  $2^n\pm 1$ . arithmetic properties have been exploited with arithmetic structures, such as diminished-1, sparse carry chain, Kogge–Stone adder, and so on, to decrease the implementation complexity of modulo addition, subtraction, and multiplication for these special moduli to an extent that is comparable with their two's complement number system counterparts. These improvements have given rise to the extensive use and continual successes in developing the balanced three moduli set  $\{2^n - 1, 2^n, 2^n + 1\}$  for the implementation of many new and existing DSP algorithms, including fast Fourier transform, discrete wavelet transform, finite and infinite impulse response filters, and digital image processing. In fact, the difficulties associated with the implementation of nonmodular operations, such as scaling and reverse conversion from residue-to-binary representation, have largely been resolved for this three moduli set.

Even though the hardware efficiency of its individual residue arithmetic operations, as well as its forward and reverse converters, some fundamental operations, such as sign detection, magnitude comparison, and overflow detection, for this moduli set remain slow and expensive. These operations are complicated to parallelize as they need the combination of multiple residue values to calcilate. To reduce the computational complexity, lookup tables are often used to store the precalculated orthogonal projections of the numbers of interest. Unfortunately, memory-based ways are difficult to pipeline. The size and number of lookup tables, as well as their access time also grow with the size of the moduli. Among these operations, sign detection is an example of a less focused

problem for this moduli set. Despite its importance as a preprocessing operation and an integral component of other intermodulo operations like magnitude comparison and overflow detection, only a handful of solutions are found in the literature.

A general theorem for sign detection in residue domain is presented, where the magnitude of an integer is first decoded from its residue representations by converting the residues into its equivalent binary representation to find the halfway point of the dynamic range. The large modulo operation in the reverse conversion is decreased by the mixed radix conversion (MRC) and to a modulo-two sum by using the fractional binary representation. Both the implementations are based on ROMs, which suffer from the aforementioned deficiencies. The most recent RNS sign detectors were designed for  $\{2^n - 1, 2^n, 2^{n+1} - 1\}$ . Although very efficient standalone, its use is limited as the efficient reverse converter, and scaler needed for a complete system implementation has not been reported for this new moduli set. The only adder-based sign detection circuits for  $\{2n - 1, 2n, 2n + 1\}$  identify the sign by either full or partial reverse conversion into the binary domain using the new Chinese remainder theorem, or through the mixed radix coefficients.

In this paper, an alternative efficient sign detection algorithm for  $\{2^n-1, 2^n, 2^n+1\}$  is proposed. The proposed technique develops the new CRT-I to greatly simplify the  $2^{2n} - 1$  scaling of residue representation into addends that can be readily achieveed by circular left shifted residues at no logic cost. The reduced dynamic range enables the sign of an integer to be calculated directly from the most significant bit (MSB) of the scaled residues with a heavily strippeddown version of a reverse converter. Another benefit of our proposed sign detector is that it can also be used as a scaler.

## **II. PRELIMINARIES AND NOTATIONS**

RNS is characterized by a set of *N* coprime numbers, called the moduli set  $\{m1, m2, ..., mN\}$ , i.e., GCD(*mi*, *m* j) =  $1 \forall i \neq j$ . Any integer *X* can be represented by an *N*-tuple (x1, x2, ..., xN) in this moduli set. Each residue  $x_i$  is the least nonnegative remainder calculated by dividing *X* by the modulus *mi*, which can be expressed mathematically as  $x_i = |X|m_i$  for i = 1, 2, ..., N. The product of all moduli is called the dynamic range *M*, i.e.,  $M = _N i = 1$   $m_i$ . Any integer *X* that lies within  $0 \leq X < M$  will have a unique residue representation.

An integer X within the dynamic range can be recovered from its residue representation (x1, x2, ..., xN) by applying the CRT

$$|\mathbf{x} = \left| \sum_{i=1}^{N} M_{i} \left| \left| M_{i}^{-1} \right|_{m_{i}} x_{i} \right|_{m_{i}} \right|_{M} \dots (1)$$

where  $M_i = M/m_i$  and  $|M-1_i|m_i$  is the multiplicative inverse of  $|M_i|m_i$ .

To represent a signed integer  $X^{n}$  in RNS, M is divided into two symmetrical half ranges for the representation of positive and negative integers. When M is even, the range of signed integers that can be definitely represented in RNS is [-M/2, M/2 - 1]. Correspondingly, for odd M, the range of definitely representable signed integers in RNS is [-(M - 1)/2, (M - 1)/2]. The signed integer  $X^{n}$  can be represented using the same residue representation as an unsigned integer X for the same moduli set. The relationship between  $X^{n}$  and X is given as follows:

$$\hat{X} = \left| \left\lfloor X + \frac{M}{2} \right\rfloor \right|_{M} - \left\lfloor \frac{M}{2} \right\rfloor_{\dots\dots(2)}$$

When  $X^{\hat{}} \ge 0$ , the residue representation of X can be mapped to that of  $X^{\hat{}}$  in the range of [0, M/2 - 1] if M is even and [0, (M - 1)/2] if M is odd. In a similar way, when  $X^{\hat{}} < 0$ , the residue representation of X can be mapped to that of  $X^{\hat{}}$  in the range of [M/2, M - 1] if M is even and [(M + 1)/2, M - 1] if M is odd. Thus, the sign of  $X^{\hat{}}$  can be identified as follows.

When *M* is even

$$\operatorname{sign}(\hat{X}) = \begin{cases} 0, & \text{if } X \in [0, (M/2) - 1] \\ 1, & \text{if } X \in [M/2, M - 1] \\ \dots \dots (3) \end{cases}$$

When *M* is odd

Fig. 1. Mapping of the half ranges of integer X in [0, M) to the half ranges of its scaled integer Y in [0, M'). Properties 1 and 2 are employed in order to simplify some arithmetic operations in the derivation of our proposed sign detection circuit for RNS  $\{2^n - 1, 2^n, 2^n + 1\}$ .

*Property 1:* The modulo  $2^n - 1$  multiplication of an *n*-bit binary number *x* and *r* exponent of two is equivalent to a circular left shift (CLS) of the binary bits of *x* by *r* positions

$$|2' x|_{2^n-1} = \text{CLS}_n(x, r)$$
 (5)

where CLSn(x, r) represents the circular shift of an *n*-bit binary number *x* by *r* bits to the left.

Property 2: As a corollary of Property 1

 $|-2^{r}x|_{2^{n}-1} = |2^{r}(2^{n}-1-x)|_{2^{n}-1} = |2^{r}\bar{x}|_{2^{n}-1} = \operatorname{CLS}_{n}(\bar{x},r)_{\ldots\ldots}(6)$ 

Where -x is the one's complement of integer *x*.

#### **III. PROPOSED SIGN DETECTION ALGORITHM**

Let  $(x_1, x_2, x_3)$  be the residue representation of an integer *X* with respect to the moduli set  $\{m_1, m_2, m_3\} = \{2^n - 1, 2^n, 2^n + 1\}$ . Since the dynamic range *M* of this moduli set can be factored into  $2^n$  and  $2^{2n} - 1$ , the sizes of the modulo operations required for identifying the sign of  $X^n$  from its equivalent residue representation of *X* can be substantially decreased by scaling  $(x_1, x_2, x_3)$  in the residue domain by  $2^{2n} - 1$ . This will map thes lower half range  $[0, 2^{3n-1} - 2^{n-1})$  of *X* to the lower half range  $[0, 2^{n-1})$  of the scaled integer *Y* and the upper half range  $[2^{3n-1} - 2^{n-1}, 2^{3n} - 2^n)$  of *X* to the upper half range  $[2^{n-1}, 2^n)$  of *Y*, as shown in Fig. 1. By minimizing the dynamic range from  $M = 2^{3n} - 2^{2n}$  to  $M' = 2^n$ , its half range can be easily identified from the MSB of the scaled integer *Y*. This new concept of sign detection in  $\{2^n - 1, 2^n, 2^n + 1\}$  can be made very efficient provided that scaling by  $2^{2n} - 1$  as well as the reverse conversion of the scaled residues into *Y* can be computed efficiently from the residues  $x_1, x_2$ , and  $x_3$ . As only the MSB of *Y* is needed for the sign detection of  $X^n$ , a full reverse conversion from  $(x_1, x_2, x_3)$  is not needed.

To simplify the scaling by 22n - 1 in the residue domain, the new CRT, also called CRT-I, is used to convert X into a weighted sum of its residues modulo 22n - 1. Corresponding to CRT-I

#### International Journal of Advance Research in Science and Engineering Volume No.06, Issue No. 09, September 2017 ARSE (0) 2319 - 8354 www.ijarse.com ISSN (P) 2319 - 8346

$$= x_3 + m_3 |k_1(x_1 - x_3) + k_2 m_1(x_2 - x_1)|_{m_1 m_2} \dots (7)$$

where  $k_1m_3 = |1|m_1m_2$  and  $k_2m_3m_1 = |1|m_2$ . With  $m_1 = 2^n - 1$ ,  $m_2 = 2^n$ , and  $m_3 = 2^n + 1$ , we have  $X = x_3 + (2^n + 1)|k_1(x_1 - x_3) + k_2(2^n - 1)(x_2 - x_1)|_{2^n(2^n - 1)}$ (8)

Χ

It can be proved that the multiplicative inverses of  $|2^n + 1|2n(2^n-1)$  and  $|2^{2n} - 1|2^n$  are given by  $k1 = 2^{2n-1} - (2^n-1)^{2n}$ (-1) and  $k^2 = -1$ , respectively. These closed form expressions of  $k^1$  and  $k^2$  are proved as follows. *Proof of k1* =  $2^{2n-1} - (2^n - 1)$ :  $k_1(2^n + 1)|2^n(2^n - 1) = |[2^{2n-1} - (2^n - 1)](2^n + 1)|2^n(2^n - 1)$  $= |2^{2n-1}(2^{n}+1) - (2^{2n}-1)|2^{n}(2^{n}-1)|$  $= |2^{3n-1} - 2^{2n-1} + 1|2^n (2^n - 1)$  $= |2^{2n-1}(2^n - 1) + 1|2^n (2^n - 1) = 1.$ 

*Proof of*  $k_2 = -1$ :

$$|k_2(2^{2n} - 1)|_{2^n} = |-1 \times (2^{2n} - 1)|_{2^n} = |-2^{2n} + 1|_{2^n} = 1$$

Substituting the values of k1 and k2 into (8), we have

$$X = x_3 + (2^n + 1) \begin{vmatrix} 2^{2n-1} - (2^n - 1)\}(x_1 - x_3) \\ - (2^n - 1)(x_2 - x_1) \end{vmatrix} \Big|_{2^n (2^n - 1)}$$
  
=  $x_3 + (2^n + 1) \begin{vmatrix} 2^{2n-1}(x_1 - x_3) \\ - (2^n - 1)(x_2 - x_3) \end{vmatrix} \Big|_{2^n (2^n - 1)} \dots (9)$ 

By scaling X by  $2^{2n}$  -1, the scaled integer Y can be obtained by

$$Y = \left\lfloor \frac{X}{2^{2n} - 1} \right\rfloor = \left\lfloor \frac{x_3}{2^{2n} - 1} \right\rfloor + \left\lfloor \frac{(2^n + 1)Z}{2^{2n} - 1} \right\rfloor \dots \dots (10)$$

where  $Z = |2^{2n-1}(x_1 - x_3) - (2^n - 1)(x_2 - x_3)|2^n(2^n - 1)$ . Since  $x_3 \in [0, 2^n]$ ,  $x_3 < 2^{2n} - 1$ . Therefore  $[(x_3/2^{2n} - 1)] = 0$ , and *Y* can be written as

$$Y = \left\lfloor \frac{(2^{n}+1)Z}{2^{2n}-1} \right\rfloor = \left\lfloor \frac{Z}{2^{n}-1} \right\rfloor$$
$$= \left\lfloor \frac{|2^{2n-1}(x_{1}-x_{3})-(2^{n}-1)(x_{2}-x_{3})|_{2^{n}(2^{n}-1)}}{(2^{n}-1)} \right\rfloor \dots \dots (11)$$

As [(|x|m1m2/m1)] = |[(x/m1)]|m2 from [11], (11) can be rewritten as

Let  $H = 2^{2n-1}(x_1 - x_3)$ . Since  $H = m[(H/m)] + |H|_m$  for any integer *H* and *m*, we have

$$H = (2^{n} - 1) \left\lfloor \frac{H}{2^{n} - 1} \right\rfloor + |H|_{2^{n} - 1} \dots \dots (13)$$

Taking mod  $2^n$  operation on both the sides of (13), we have

$$|H|_{2^{n}} = \left| (2^{n} - 1) \left\lfloor \frac{H}{2^{n} - 1} \right\rfloor \right|_{2^{n}} + ||H|_{2^{n} - 1}|_{2^{n}} \dots \dots (14)$$

Since  $|H|_2 n = |2^{2n-1}(x_1 - x_3)|2^n = 0$  and  $|2^n - 1|_2 n = -1$ 

Substituting (15) into (12), we have

 $Y = ||H|_{2^{n}-1} + x_{3} - x_{2}|_{2^{n}}$ =  $||2^{2n-1}(x_{1} - x_{3})|_{2^{n}-1} + x_{3} - x_{2}|_{2^{n}}.....(16)$ 

If  $Y \in [0, 2^{n-1})$ , X falls in the lower half range of M and  $(x_1, x_2, x_3)$  denotes a positive integer, i.e.,  $X^* \ge 0$ . Otherwise, if  $Y \in [2^{n-1}, 2^n)$ , X falls in the upper half range of M and  $(x_1, x_2, x_3)$  represents a negative integer, i.e.,  $X^* < 0$ .

## **3.1 HARDWARE IMPLEMENTATIONS**

The residues x1, x2, and x3 can be denoted in a binary form as  $x_1 = x_{1,n-1}x_{1,n-2} \dots x_{1,0}$ ,  $x_2 = x_{2,n-1}x_{2,n-2} \dots x_{2,0}$  and  $x_3 = x_{3,n} x_{3,n-1} \dots x_{3,0}$ , respectively, where  $x_{i,j}$  represents the *j* th bit of the residue  $x_i$ . The binary vectors of x1 and x2 are of *n* bits but the binary vector of  $x_3$  is of n + 1 bits. In (16), one of the terms in the modulo  $2^n - 1$  sum involves the operation  $|-2^{2n-1} x_3|2^n-1$ , which cannot be directly implemented by Property 2, since  $x_3$  has n+1 bits. To apply the CLS property on the one's complement of  $x_3$  as in (6),  $x_3$  is expressed as  $x_3 = 2^n x_{3,n} + x_{3,n-1}x_{3,n-2} \dots x_{3,0}$ . Since  $|2^n x_{3,n}|2^n-1 = x_{3,n}$ , the MSB  $x_{3,n}$  of  $x_3$  can be logically OR with x3,0 to form an *n*-bit binary vector  $x'_3 = |x_3|2^n-1 = |x_{3,n-1}x_{3,n-2} \dots x'_{3,0}|2^n-1$ , where  $x'_{3,0} = x_{3,0} \vee x_{3,n}$  and  $\vee$  denotes a logical OR operator.  $|H|_2n-1$  in (16) can then be implemented using the CLS operations of Properties 1 and 2 to obtain

where

$$u_{1} = |2^{2n-1}x_{1}|_{2^{n}-1} = \operatorname{CLS}_{n}(x_{1}, 2n-1) = \underbrace{x_{1,0}}_{1} \underbrace{x_{1,n-1} \dots x_{1,1}}_{n-1} \dots \dots (18)$$
$$u_{2} = |2^{2n-1}\bar{x}_{3}|_{2^{n}-1} = \operatorname{CLS}_{n}(\bar{x}_{3}', 2n-1) = \underbrace{\bar{x}_{3,0}'}_{1} \underbrace{\bar{x}_{3,n-1} \dots \bar{x}_{3,1}}_{n-1} \dots \dots (19)$$

The term  $|u_1 + u_2| 2^n - 1$  can be expressed as

 $|u_{1} + u_{2}|_{2^{n}-1} = \begin{cases} |u_{1} + u_{2} + 1|_{2^{n}}, & \text{if } u_{1} + u_{2} \ge 2^{n} - 1\\ u_{1} + u_{2}, & \text{otherwise} & \dots \dots (20) \end{cases}$   $u_{1} \quad u_{2} \\ \downarrow n \quad \downarrow n \\ g_{i} \text{ and } p_{i} \text{ Generator} \\ \hline \\ Generator \\ C_{1} \quad \downarrow C_{2} \end{cases}$ 

### Fig. 2. Generation of carry-in signal $c_{\rm in}$

## International Journal of Advance Research in Science and Engineering

Volume No.06, Issue No. 09, September 2017 www.ijarse.com IJARSE ISSN (O) 2319 - 8354 ISSN (P) 2319 - 8346

Hence,  $||u_1 + u_2|^{2^n} - 1|^{2^n} = |u_1 + u_2 + c_{in}|^{2^n}$ , where  $cin \in \{0, 1\}$ . As  $|-x_2|^{2^n} = 2_n - x^2 = x_2 + 1$ , (17) can be written as

 $Y = |u_1 + u_2 + c_{\text{in}} + x_3 + \bar{x}_2 + 1|_{2^n}$ (21)

The generation of the carry-in signal  $c_{in}$  is shown in Fig. 2. The

condition  $u_1 + u_2 \ge 2^n$  is detected by  $C_1 = 1$  and the signal  $C_1$  can be generated by parallel prefix operators. As an example, the carry signal  $C_1$  for n = 8 can be generated by the circuit shown in Fig. 3. The condition  $u_1+u_2 = 2^n-1 = \{11 \dots 11\}$  n can be identified by  $C_2 = 1$ .  $C_2$  is generated by  $w \land v$ , where  $w = \bigwedge_{i=0}^{n-1} g_i$  and  $v = p_{n-1}:0 = \bigwedge_{i=0}^{n-1} p_i$ , where  $\land$  denotes a logical AND operator. The signals  $g_i$  and  $p_{n-1:0}$  have already been generated in the computation of C1. Accordingly, the condition  $u_1+u_2 \ge 2^n - 1$  for c in = 1 can be detected by

$$c_{\rm in} = C_1 \vee C_2....(22)$$

The two addends,  $u^2$  and  $x^3$ , in (21) can be further simplified as follows:

Fig. 4. Proposed sign detection architecture for  $\{2^n - 1, 2^n, 2^n+1\}$ 

# International Journal of Advance Research in Science and Engineering Volume No.06, Issue No. 09, September 2017 IJA www.ijarse.com

When  $x_{3,n} = 0$ ,  $x'_{3,0} = x_{3,0} \lor 0 = x_{3,0}$ . Then  $|u_2 + x_3|_{2^n} = |x_{3,0}x_{3,n-1}x_{3,n-2} \dots x_{3,1} - \bar{x}_{3,0}|_{2^n}$  (24) When  $x_{3,n} = 1$ , since  $x_3 \in [0, 2n]$ ,  $x_{3,n-1}x_{3,n-2} \dots x_{3,0} = 00 \dots 0$ . Hence,  $x'_{3,0} = x_{3,0} \lor x_{3,n} = 1$  and

$$|u_{2} + x_{3}|_{2^{n}} = \left| \underbrace{100 \dots 0}_{n} - 1 \right|_{2^{n}} = \underbrace{011 \dots 1}_{n}$$
$$= \left| \underbrace{x_{3,0}x_{3,n}x_{3,n} \dots x_{3,n}}_{n} - \bar{x}_{3,0} + x_{3,n} \right|_{2^{n}}$$
$$= \left| \underbrace{x_{3,n}00 \dots 0}_{n} - \bar{x}_{3,0} \right|_{2^{n}} \dots \dots (25)$$

To satisfy both (24) and (25)

 $|u_2 + x_3|_{2^n} = |u_3 - \bar{x}_{3,0}|_{2^n}$ .....(26)

where the *n*-bit binary vector  $u_3$  is given by

 $u_3 = (x_{3,0} \lor x_{3,n}) x_{3,n-1} x_{3,n-2} \dots x_{3,1} \dots (27)$ 

Substituting (26) into (21), we have

 $Y = |u_1 + u_3 + \bar{x}_2 + c_{\text{in}} + 1 - \bar{x}_{3,0}|_{2^n} \dots (28)$ 

If  $x_{3,0} = 1$ ,  $1 - x_{3,0} = 1$ , and if  $x_{3,0} = 0$ ,  $1 - x_{3,0} = 0$ . Hence, the term  $1 - x_{3,0}$  in (28) can be replaced by  $x_{3,0}$  and

$$Y = |u_1 + u_3 + \bar{x}_2 + c_{\text{in}} + x_{3,0}|_{2^n} \dots (29)$$

The sign of  $X^{\hat{}}$  can be identified by the MSB of Y. An *n*-bit carry save adder (CSA) can be used to add the three *n*-bit operands,  $u_1$ ,  $u_3$ , and  $x_2$ , to produce an *n*-bit sum  $A = a_{n-1}a_{n-2} \dots a_0$  and an *n*-bit carry vector  $B = b_{n-1}b_{n-2} \dots b_1b_0$ . Due to the modulo 2n addition, the final carry output bit bn of the CSA need not be generated. As b0 = 0, it can be replaced by x3,0 of (29) before the MSB of Y is calculated by a simplified parallel prefix adder of A and B with the input carry bit  $c_{-1} = c_{in}$ . The prefix adder is simplified by keeping only the carry generation network for the computation of carry signal  $c_{n-1}$ , from which the sign of  $X^{\hat{}}$  can be identified by  $sign(\hat{X}) = a_{n-1} \oplus b_{n-1} \oplus c_{n-1}$ . The architecture of the proposed sign detector is shown in Fig. 4, where the circuit diagram for the simplified prefix adder is depicted in Fig. 5 for n = 8.

Fig. 5. Simplified prefix adder for n = 8

#### Fig. 6. Computation of Y for Example 1

*Example 1:* For n = 5,  $\{m_1, m_2, m_3\} = \{31, 32, 33\}$ ,  $M = 31 \times 32 \times 33 = 32736$ , and M/2 = 16368. The signed integer  $X^* = -11161$  can be denoted by the residue representation  $(x_1, x_2, x_3) = (30, 7, 26)$  according to the unsigned integer X = 21575 in the same moduli set. The binary representation of the residues are  $x_1 = 111102$ ,  $x_2 = 001112$ , and  $x_3 = 0110102$ . According to (18), (19), and (27),  $u_1 = 011112$ ,  $u_2 = 100102$ , and  $u_3 = 011012$ . Also,  $x_{3,0} = 0$ . Since  $u_1 + u_2 = 01111 + 10010 = 33 > 32$ , C1 = 1. Since 33 = 31, C2 = 0. According to (22),  $c_{in} = C_1 \vee C_2 = 1$ . The calculation of *Y* in (29) is illustrated in Fig. 6. Since MSB of Y = 1, the integer  $X^*$  represented by (30, 7, 26) is negative.

## **IV. SYNTHESIS AND SIMULATION RESULTS**

The proposed razor latch is designed with the XILINX ISE 14.5 simulation tool and implemented with Verilog HDL. The RTL diagram and simulation results are displayed below.

## **VI. CONCLUSION**

In this paper, an efficient fast sign detection algorithm for the residue number system moduli set  $\{2^{n}-1, 2^{n}, 2^{n}+1\}$  is presented. The proposed algorithm which allows parallel implementation and include modulo 2n additions. Based on existing sign detection algorithm, an efficient sign detection algorithm is proposed. The sign detection unit can be implemented using one carry save adder, one comparator and one prefix adder. Here efficiency achieved is better than other algorithm for sign detection. Adder based sign detectorwas designed by the Verilog HDL synthesized in Xilinx ISE 14.5.

## **VII. FUTURE SCOPE**

Arithmetic designs are developed and holded with these proposed methods of reverse converters in RNS formulation. Finally with these conditional procure positions of adders obtain the eventual levels of area, power and performance.
