### ABSTRACT:

In the present study, effect of various factors was studied for the isolation of protoplasts from the mesophyll cells of four superior temperate mulberry varieties viz. *Morus alba* Chinese white, *Morus alba* var. Ichinose, *Morus multicaulis* var. Goshierami and an interspecific hybrid i.e. PPR-1 (Pampore-1). Among all the factors, concentration and combination of enzymes used, concentration of osmoticum and duration of enzymatic treatments were found to be major factors effecting the isolation of viable protoplasts in maximum number. Among the different combinations of enzyme solutions tested, the maximum yield of viable protoplasts ( $5.171 \pm 0.354 \times 10^6$  g<sup>-1</sup> fresh weight and  $6.051 \pm 0.424 \times 10^6$  g<sup>-1</sup> fresh weight) was obtained from the enzymatic combination of 2% Cellulase, 0.5% Macerozyme and 0.2% Pectinase for incubating the leaf pieces for 8 Hrs and 10 Hrs duration with 80 RPM (Rotations Per Minute) on rotary shaker at 26° C from Goshierami & PPR-1 varieties respectively. Similarly among the different concentrations of osmoticum (Mannitol) tested, 13% of Mannitol (CPW-13M) has given the maximum viable protoplasts of 72%, 77%, 88%, & 92% in Ichinose, Chinese white, Goshierami and PPR-1 respectively. Viability of isolated protoplasts was carried out by using 0.2% Evans Blue stain.

**Keywords:** Cellulase, Mesophyll cells, Protoplasts, Temperate mulberry, Viability.

### 1. Introduction

In plants producing full hybrids is not easy because of sexual incompatibility barriers between desired individuals. This has often proved to be a serious threat in crop improvement programs through conventional breeding programmes. Whereas in somatic hybridization, protoplasts of any two mulberry varieties can be fused irrespective of their species type and breeding season, from the fused protoplasts a somatic hybrid can be raised due to their totipotency nature.

Protoplasts are the naked plant cells from which cell wall has been removed, but the plasma membrane is intact. Both from the isolated protoplasts and from their fusion product, a somatic hybrid, can be regenerated into whole plantlets through the regeneration studies. In somatic hybridization due to fusion of protoplasts derived from different mulberry varieties, there is high possibility of genomic combinations which can lead to the production of somatic hybrids with more desirable characters [1]. It allows us to combine entire genomes from the sexually incompatible parents and expected to result in hybrids which are superior in characters [2, 3].

In recent days, as much success was reported in isolation of protoplasts from different plant species by enzymatic method [4-9], we have also carried the enzymatic method and identified the effect of various factors for the isolation of protoplasts from the mesophyll cells of four superior temperate mulberry varieties: *Morus alba* var. Ichinose; *Morus alba* var. Chinese White, *Morus multicaulis* var. Goshierami and an interspecific hybrid i.e. PPR-1 (Pampore-1).

So, through this research paper we are reporting about the effect of various factors on protoplast isolation from the superior temperate mulberry varieties by enzymatic method.

## 2. Materials & Methods

### 2.1 Plant Material

Fully expanded leaves from the *in vitro* shootlets of Goshierami, Ichinose, Chinese white and PPR-1 were used in this research study.

### 2.2 Enzymes:

Cellulase Onozuka R-10, Macerozyme R-10 and Pectinase enzymes were procured from Himedia and used in this study.

### 2.3 Isolation of Protoplasts:

Fully expanded leaves of 40- 50 days old were excised from the *in vitro* shootlets of Ichinose, Chinese white, Goshierami and PPR-1 mulberry varieties with a sterile scalpel blade in aseptic conditions under laminar air flow cabinet and they were cut into small pieces of 1-2 mm in size. Leaf pieces of about 1 gram fresh weight were incubated in sterile conical flask (100 ml capacity) with 15 ml of filter sterilized enzyme solution (2% cellulase, 0.5% macerozyme and 0.2% pectinase) which were prepared in CPW-13M solution with 5.6 pH for 6-12 hrs duration on rotary shaker at 80 RPM in dark conditions at 26°C (Table-1 & Table-2). During the incubation period, pectin material present in the intracellular spaces get degraded by macerozyme and pectinase enzymes and cellulosic material of cell walls by cellulase enzyme leading to release of protoplasts from the mesophyll cells.

## 2.4 Purification of Isolated Protoplasts:

The isolated protoplasts were initially filtered by using steel mesh with a pore size of  $45\mu$ . The obtained filtrate was collected in a 20 ml sterile screw cap centrifuge tube and centrifuge at 1000 RPM for 5 minutes. After centrifugation, supernatant was discarded. Impurities like cell debris were removed from the pellet of protoplasts by carrying out centrifugation at 600 rpm for 5 Minutes after the addition of 10 ml of 20% sucrose solution (CPW-20S) (Table-3). After centrifugation, protoplasts were obtained as a distinct band, which were collected into a separate sterile screw cap centrifuge tube with the help of a pasteur pipette. The collected protoplasts were suspended in 5ml of CPW-13 M solution to maintain them in viable state.

## 2.5 Yield and Viability of Isolated protoplasts:

Initially to determine the yield of protoplasts, 10  $\mu$ l of suspended protoplasts solution was taken on a clean glass slide and observed under the compound light microscope in different magnifiable lenses and results were expressed as number of protoplasts per gram fresh weight of leaf. For checking the viability and yield of viable protoplasts, to the suspended protoplasts solution (1 ml), 20  $\mu$ l of 0.2 % Evans blue (20 mg/10 ml sterile distilled water) solution was added and incubated for 2 minutes. Then 10  $\mu$ l of 0.2% Evans Blue stain treated protoplast solution were placed on a haemocytometer slide and observed under compound light microscope and their yield results were expressed as number of protoplasts per gram fresh weight of leaf. Viability results were expressed as percentage which is determined by the number of viable (unstained) protoplasts to that of non-viable (stained) protoplasts.

## 2.6 Statistical Analysis:

The data obtained from this research study was the mean of 3 replications and the data was statistically analyzed by using SPSS Version 17 (SPSS Inc., Chicago, USA). The mean values were compared by Tukey's tests at the 5% level of significance. All means are represented with standard error.

## 3. Results & Discussion:

In this research study, we have identified the effect of various factors in isolation of protoplasts from the mesophyll cells of four superior mulberry varieties viz. *Morus alba* var. Chinese white, *Morus alba* var. Ichinose, *Morus multicaulis* var. Goshierami and an interspecific hybrid i.e. PPR-1 (Pampore-1). Several authors have reported about the isolation of protoplasts from the mesophyll cells of tropical and subtropical mulberry [10-19], but there is scanty information on the isolation of protoplasts from the temperate mulberry varieties. And to the best of our knowledge this is the first report on protoplast isolation from temperate mulberry varieties.

Initially when different combinations of enzyme solutions tested, the maximum yield of viable protoplasts ( $5.171 \pm 0.354 \times 10^6$  g<sup>-1</sup> fresh weight and  $6.051 \pm 0.424 \times 10^6$  g<sup>-1</sup> fresh weight) was obtained from the combination of 2% Cellulase, 0.5% Macerozyme and 0.2% Pectinase for incubating the leaf pieces for 8 Hrs in

Goshoerami and for 10 Hrs in PPR-1 respectively (Fig.1). Other two varieties (i.e. Chinese White and Ichinose) also yield the protoplast with the same set of factors and conditions as PPR-1 but the count of protoplasts in these two varieties is not comparable as that of PPR-1 (Table-4). Similar to our findings, other researchers [12, 16 &19] also used 2% cellulase in isolation of maximum number of protoplasts from mesophyll cells of different tropical and sub-tropical mulberry varieties.

As the intactness of plasmembrane and viability of isolated protoplasts depends on the appropriate concentration of osmoticum used, we have tested several concentrations of mannitol as osmoticum in our study. Among the different concentrations tested, 13% of Mannitol (CPW-13M) has given the maximum viable protoplasts of 72%, 77%, 88%, & 92% in Ichinose, Chinese white, Goshoerami and PPR-1 respectively. Viability of isolated protoplasts was ascertained by using 0.2% Evans Blue stain, after staining the viable protoplasts have excluded the stain and remained unstained, whereas the non-viable or dead protoplasts have retained the stain and stained blue in colour (Fig-2A & Fig-2D).

Enzymatic incubation for more than 10 hrs has resulted in the increase of yield of protoplasts from all the varieties but the viability has reduced. Similar to our findings, more than 9 hours of enzymatic treatment duration has decreased the viability of isolated protoplasts in three cultivars of mulberry i.e. K2, S13 and S36[20].

#### 4. Figures and Tables

**Fig.1:Microscopic views (under 40 x objective lenses) of isolated protoplasts from mesophyll cells of temperate mulberry varieties viz. A) PPR-1 B) Chinese White C) Ichinose D) Goshoerami by using enzymatic combination of 2% cellulase, 0.5% macerozyme and 0.2% pectinase**

**Fig.2:- Microscopic views of evaluation of viability of isolated protoplasts with Evan's blue (0.2%) under 40 x objective lenses**

- A) Viable (unstained) and Non-viable (stained) protoplasts of PPR-1
- B) Viable (unstained) and Non-viable (stained) protoplasts of Chinese White
- C) Viable (unstained) and Non-viable (stained) protoplasts of Ichinose
- D) Viable (unstained) and Non-viable (stained) protoplasts of Goshierami

Represented Data is the mean and standard error of three replication. Mean $\pm$ standard errors followed by same letter is not significantly different at P=0.05 according to SPSS Version 17 (SPSS Inc., Chicago, USA) and means were compared using Tukey's tests at the 5% level of significance

### Conclusion:

Overall by considering all the factors the combination of enzyme solution (2% Cellulase, 0.5% Macerozyme and 0.2% Pectinase), duration of enzyme treatment (8-10 Hrs) and osmoticum concentration (13% Mannitol) were found to be the major factors influencing the isolation of protoplasts in maximum number from the mesophyll cells of temperate mulberry varieties. The developed protocol with standardized parameters will be utilized in isolation of protoplasts from temperate mulberry, which can be used as raw materials for somatic hybridization studies and improvement of mulberry through genetic engineering approaches.

### 5. Acknowledgements

Authors thank Central Silk Board, Ministry of Textiles, Government of India and Director, Central Sericultural Research & Training Institute, Pampore (J&K), India for providing financial support under the project Code:3571. Authors also thankCORD, University of Kashmir for providing all the necessary facilities in carrying out this research work.
